Stochastic Lambda-Calculus

Dana S. Scott, FBA, FNAS

University Professor Emeritus
Carnegie Mellon University
Visiting Scholar
University of California, Berkeley
Combinatory logic is an abstract science dealing with objects called combinators. What their objects are need not be specified; the important thing is how they act upon each other.

One is free to choose for one's "combinators" anything one likes (for example, computer programs). Well, I have chosen birds for my combinators — motivated, no doubt, by the memory of the late Professor Haskell Curry, who was both a great combinatory logician and an avid bird-watcher.

The main reason I chose combinatory logic for the central theme of this book was not for its practical applications, of which there are many, but for its great entertainment value. Here is a field considered highly technical, yet perfectly available to the general public; it is chock-full of material from which one can cull excellent recreational puzzles, and at the same time it ties up with fundamental issues in modern logic.

What could be better for a puzzle book? (Preface, p. x.)

Raymond M. Smullyan. To Mock a Mockingbird and Other Logic Puzzles
Some Other Quotations

There is, however, one feature that I would like to suggest should be incorporated in the machines, and that is a random element.

– Alan Turing, Intelligent Machinery, A Heretical Theory

83. What is the difference between a Turing machine and the modern computer? It’s the same as that between Hillary’s ascent of Everest and the establishment of a Hilton hotel on its peak.

60. Dana Scott is the Church of the Lattice-Way Saints.

30. Simplicity does not precede complexity, but follows it.

– Alan Perlis, Epigrams on Programming
**Church's $\lambda$-Calculus**

**Definition.** $\lambda$-calculus — as a formal theory — has rules for the *explicit definition* of functions via well known equational axioms:

$\alpha$-conversion

$$\lambda x.[...x...] = \lambda y.[...y...]$$

$\beta$-conversion

$$(\lambda x.[...x...])(T) = [...T...]$$

$\eta$-conversion

$$\lambda x.F(x) = F$$

**NOTE:** The third axiom will be dropped in favor of a theory employing properties of a *partial ordering.*
The Enumeration Operator Model

**Definitions.**

1. **Pairing:** $(n,m) = 2^n(2m+1)$.

2. **Sequence numbers:** $\langle \rangle = 0$ and
   $$\langle n_0, n_1, \ldots, n_k \rangle = (\langle n_0, n_1, \ldots, n_{k-1} \rangle, n_k).$$

3. **Sets:** $\text{set}(0) = \emptyset$ and $\text{set}((n,m)) = \text{set}(n) \cup \{m\}$.

4. **Kleene star:** $X^* = \{n \mid \text{set}(n) \subseteq X\}$, for sets $X \subseteq \mathbb{N}$.

**Definition.** The model is given by these definitions on the powerset of the set integers, $\mathcal{P}(\mathbb{N})$:

**Application:**

$$F(X) = \{m \mid \exists n \in X^*. (n,m) \in F\}$$

**Abstraction:**

$$\lambda X. [...X...] =$$

$$\{0\} \cup \{(n,m) \mid m \in [... \text{set}(n) ...]\}$$
What is the Secret?

(1) The powerset $\mathcal{P}(\mathbb{N}) = \{ x \mid x \subseteq \mathbb{N} \}$ is a topological space with the sets $\mathcal{U}_n = \{ x \mid n \in x^* \}$ as a basis for the topology.

(2) Functions $\Phi: \mathcal{P}(\mathbb{N})^n \rightarrow \mathcal{P}(\mathbb{N})$ are continuous iff, for all $m \in \mathbb{N}$, we have $m \in \Phi(x_0, x_1, \ldots, x_{n-1})$ iff there are $k_i \in x_i^*$ for each of the $i < n$, such that $m \in \Phi(\text{set}(k_0), \text{set}(k_1), \ldots, \text{set}(k_{n-1}))$.

(3) The application operation $F(x)$ is continuous as a function of two variables.

(4) If the function $\Phi(x_0, x_1, \ldots, x_{n-1})$ is continuous, then the abstraction term $\lambda x_0. \Phi(x_0, x_1, \ldots, x_{n-1})$ is continuous in all of the remaining variables.

(5) If $\Phi(x)$ is continuous, then $\lambda x. \Phi(x)$ is the largest set $F$ such that for all sets $T$, we have $F(T) = \Phi(T)$. And, therefore, generally $F \subseteq \lambda x. F(x)$.

NOTE: This model could easily have been defined in 1957!!
It clearly satisfies the rules of $\alpha$, $\beta$-conversion (but not $\eta$).

Some Lambda Properties

**Theorem.** For all sets of integers $F$ and $G$ we have:

\[ \lambda X. F(X) \subseteq \lambda X. G(X) \text{ iff } \forall X. F(X) \subseteq G(X), \]

\[ \lambda X. (F(X) \cap G(X)) = \lambda X. F(X) \cap \lambda X. G(X), \]

and

\[ \lambda X. (F(X) \cup G(X)) = \lambda X. F(X) \cup \lambda X. G(X). \]

**Definition.** A continuous operator $\Phi(X_0, X_1, \ldots, X_{n-1})$ is *computable* iff in the model this set is \textbf{RE}:

\[ F = \lambda X_0 \lambda X_1 \ldots \lambda X_{n-1}. \Phi(X_0, X_1, \ldots, X_{n-1}). \]
How to do Recursion?

Three Basic Theorems.

- All pure \( \lambda \)-terms define \textit{computable} operators.
- If \( \Phi(x) \) is continuous and if we let \( \nabla = \lambda x. \Phi(x(x)) \), then the set \( P = \nabla(\nabla) \) is the \textit{least fixed point} of \( \Phi \).
- The least fixed point of a \textit{computable} operator is computable.

A Principal Theorem. These computable operators:

\[
\text{Succ}(x) = \{ n+1 \mid n \in x \},
\]

\[
\text{Pred}(x) = \{ n \mid n+1 \in x \}, \text{ and}
\]

\[
\text{Test}(Z)(X)(Y) = \{ n \in X \mid 0 \in Z \} \cup \{ m \in Y \mid \exists k. k+1 \in Z \},
\]

together with \( \lambda \)-calculus, suffice for defining \textit{all} \textit{RE sets}. 

Gödel Numbering

**Theorem.** There is a computable \( V = \lambda x. V(x) \) where

(i) \( V(\{0\}) = \lambda y. \lambda x. y, \)
(ii) \( V(\{1\}) = \lambda z. \lambda y. \lambda x. z(x)(y(x)), \)
(iii) \( V(\{2\}) = \text{Test}, \)
(iv) \( V(\{3\}) = \text{Succ}, \)
(v) \( V(\{4\}) = \text{Pred}, \) and
(vi) \( V(\{4 + (n, m)\}) = V(\{n\})(V(\{m\})). \)

**Theorem.** Every *recursively enumerable set* is of the form \( V(\{n\}). \)

**NOTE:** The operator \( V \) is the analogue of the Universal Turing Machine.
Inseparable Sets?

**Definition.** Modify the definition of $V$ via finite approximations:

(i) $V_k({n}) = V({n}) \cap \{i \mid i < k\}$ for $n < 5$, and

(ii) $V_k({4 + (n,m)}) = V_k({n})(V_k({m}))$.

**Theorem.** Each $V_k({n}) \subseteq V_{k+1}({n})$ is finite, the predicate $j \in V_k({n})$ is recursive, and we have:

$$V({n}) = \bigcup_{k < \infty} V_k({n}).$$

**Theorem.** The sets $\mathcal{L}_0$ and $\mathcal{L}_1$ are recursively enumerable, disjoint, and recursively inseparable:

$\mathcal{L}_0 = \{n \mid \exists j \ [0 \in V_j({n})(n) \land 1 \notin V_j({n})(n)]\}$

$\mathcal{L}_1 = \{n \mid \exists k \ [1 \in V_k({n})(n) \land 0 \notin V_k({n})(n)]\}$
How to Randomize?

Definition. By a random variable we mean a function
\[ X : [0, 1] \to \mathcal{P}(\mathbb{N}), \]
where, for \( n \in \mathbb{N} \), the set \( \{ t \in [0, 1] \mid n \in X(t) \} \)
is always Lebesgue measurable.

Theorem. The random variables over \( \mathcal{P}(\mathbb{N}) \) are closed under (pointwise) application and form a model for the \( \lambda \)-calculus — expanding the original model.

This idea is the beginning of putting a Boolean-valued Logic on random variables using the complete Boolean algebra of measurable sets modulo sets of measure zero. This new model gives us a programming language with randomized parameters.
Randomized Coin Tossing

Definition. A coin flip is a random variable $F: [0, 1] \rightarrow \{\{0\}, \{1\}\}$, it is fair iff $\mu[F = \{0\}] = 1/2$.

Definition. Pairing functions for sets in $\mathcal{P}(\mathbb{N})$ can be defined by these enumeration operators:

$\text{Pair}(X)(Y) = \{2n \mid n \in X\} \cup \{2m+1 \mid m \in Y\}$

$\text{Fst}(Z) = \{n \mid 2n \in Z\}$ and $\text{Snd}(Z) = \{m \mid 2m+1 \in Z\}$.

Definition. A tossing process is a random variable $T$ where $\text{Fst}(T)$ is a fair coin flip and where $\text{Snd}(T)$ is another tossing — with the successive flippings all being mutually independent.

The problem with using a coin-tossing process $T$ in an algorithm is that once $\text{Fst}(T)$ has been looked at, then that toss should be discarded, and only the new coins from $\text{Snd}(T)$ should be used in the future.
A Prototype Algorithm Language

Perhaps a solution is always to evaluate programs in the order in which expressions are written. Let's try a very sparse language.

\[ V_i \] — a **variable**

\[ M(N) \] — an **application**

\[ \lambda V_i . M \] — an **abstraction**

\[ M \oplus N \] — a **stochastic choice**

Let \( V_i = M \text{ in } N \) — a **direct valuation**

The idea here is that the text \( M \) is evaluated in an **environment** giving the values of free variables. Then the result is passed on to a **continuation**. In case a random choice is needed, the **tossing** process is called. We will try to employ a **continuation semantics** where the denotation of a program uses the \( \lambda \)-calculus formulation:

\[ \langle M \rangle (\text{env}) (\text{cont}) (\text{toss}) \]
The Semantical Equations

- \( \langle V_i \rangle (E)(C)(T) = C(E(\{i\}))(T) \)
- \( \langle M(N) \rangle (E)(C)(T) = \langle M \rangle (E)(\lambda X. \langle N \rangle (E)(\lambda Y. C(X(Y))))(T) \)
- \( \langle \lambda V_i . M \rangle (E)(C)(T) = C(\lambda X. \langle M \rangle (E[X/{i}]))(T) \)
- \( \langle M \oplus N \rangle (E)(C)(T) = \text{Test}(Fst(T))(\langle M \rangle (E))(\langle N \rangle (E))(C)(Snd(T)) \)
- \( \langle \text{Let } V_i = M \text{ in } N \rangle (E)(C)(T) = \langle N \rangle (E[\langle M \rangle (E)/{i}]) (C)(T) \)

Running a (closed) program means evaluating:

\[ \langle M \rangle (\emptyset) (\lambda X.\lambda Y.X)(T) \]

The semantics and model as presented here, however, are only sketches. Examples of randomized algorithms need to be worked out, as well as good methods of proving probabilistic properties of programs.
An Absoluteness Theorem

**Theorem.** If a closed program has a *non-random* value, then the value is the same for all tossing processes.

**Proof Idea:** Working within Boolean-valued logic over the measure algebra of Lebesgue sets modulo sets of measure zero, all tossing processes are the same up to a measure-preserving automorphism of the measure algebra.
A PLEA FOR HELP!

Let’s find some good applications for this model with random variables!
